Abstract

陈鸿翔 (11310075)

1 Explain the measurement of quantum states

A quantum system in state $|\phi\rangle$ upon measurement \mathcal{A} , will collapse to one of the eigenstates (for example, $|a\rangle$) of the corresponding operator A . The probability of collapsing to this eigenstate is determined by $|\langle\phi|a\rangle|^2$.

2 Solve the eigenvalues and eigenfunctions of σ_z

Physically we have a spin up eigenstate and a spin down eigenstate. So the answer can be guessed. They are just: $\alpha \begin{pmatrix} 1 \\ 0 \end{pmatrix}$, with eigenvalue 1, and $\beta \begin{pmatrix} 0 \\ 1 \end{pmatrix}$, with eigenvalue -1 . Here α, β are arbitrary nonzero complex constants.

3 Prove some commutation relationships

Proof. With Einstein summation convention, we can write

$$L_i = \epsilon_{ijk} r_j p_k, \quad [r_j, p_k] = i\hbar \delta_{jk} \quad (3.0.1)$$

Then

$$\begin{aligned} [L_i, r_l] &= \epsilon_{ijk} [r_j p_k, r_l] = \epsilon_{ijk} r_j [p_k, r_l] = -i\hbar r_j \epsilon_{ijk} \delta_{kl} \\ &= -i\hbar r_j \epsilon_{ijl} = i\hbar \epsilon_{ilj} r_j \end{aligned} \quad (3.0.2)$$

Therefore, $[L_i, r_i] = 0$ since $\epsilon_{iij} \equiv 0$. \square
